**ABSTRACT**

In response to the propagation of bacteria resistant to many antibiotics, the discovery of new and more efficient antibacterial agents is primordial. The present study was designed to evaluate the antimicrobial activity of three extracts of medical plants, *Cichorium intybus*, *Dorema aucheri* and *Prangos ferulacea* against some food born pathogens. These extracts were first prepared with methanol. The antimicrobial activity of the extracts was then assessed using the agar-well diffusion method and microtiter broth dilution method against nine bacterial strains i.e. *Staphylococcus, Bacillus subtilis, Bacillus cereus, Listeria monocytogenes, Escherichia coli, Citrobacter freundii, Salmonella enteritidis, Enterococcus aeroguns and Klebsiella pneumoniae*. The studied extracts displayed various degrees of antibacterial activities. The extracts of *Dorema aucheri* showed the best spectra of activity. In conclusion, we can use these extracts as food additives and antibacterial preservatives after improvement at food safety studies.

**Key words:** *Cichorium intybus*, *Dorema aucheri*, *Prangos ferulacea*, Antimicrobial activities, Food born pathogens

**INTRODUCTION**

Nature has provided a complete store of remedies to cure all ailments of human. The natural or herbal remedies are still the backbone of medicines. Phytotherapy is a medicinal practice based on the use of herbal plants and their extracts[1]. Single and poly herbal preparations have been used numerously throughout history for the treatment of various diseases [2]. The increased demand for safe and natural food, without chemical preservatives, provokes many researchers to investigate the antimicrobial effects of herbal compounds [3]. A large number of diverse types of plants grow wild in different parts of Iran. The use of different parts of several medicinal plants to cure specific diseases has been in vogue from ancient times in Iran. Some of these plants are; *Cichorium intybus*, *Dorema aucheri* and *Prangos ferulacea*.

*Cichorium intybus* L. (Chicory) belongs to the family Asteraceae and it is a small aromatic biennial or perennial herb. The whole plant contains a number of medicinally important compounds such as inulin, esculin, volatile compounds (monoterpenes and sesquiterpenes), coumarins, flavonoids and vitamins [4]. In traditional medicine, all parts of the plant specially root and leaves are used as diuretic, laxative, antibilious, antipyretic, blood purification and strengthen of the stomach. It is also used as an appetizer as well as in the treatment of hepatic failure, jaundice, intermittent fever and mild states of chronic skin diseases [5].Leaves of chicory are good sources of phenols, vitamins A and C as well as potassium, calcium, and phosphorus [6]. Furthermore, chicory in rich cichoric acid may
stimulate the immune system as well as prevents inflammation and bacterial infections to a limited extent [7]. A careful review of literature has shown that little data are available on the antimicrobial properties of chicory leaves extracts.

*Dorema aucheri* is one of the endemic plant species with economic and ecological values, growing in central Zagros mountains of the southwest of Iran. Increasing anthropogenic pressures, including deforestation, re-forestation, intensification of agriculture, drainage of wetland, have already had a great impact on the growth, survival and distribution of native species in Iran, especially the rare and endemic species [8]. This plant grows well in subhumid to humid climate. Various members of *Dorema*, are effective antispasmodic, expectorant diuretic, carminative, diaphoretic, vasodilator [9, 10], antimicrobial and antifungal [11,12], hepatoprotector[13] and are intensively used as a green vegetable or as a popular medicine for treatment of many human diseases [14]. Crude extract of the plant that demonstrated antioxidant activity and anti-lipidemic effects [15]; the resin that exudes from punctures in the stem caused by insect attack has similar impacts.

The genus Prangos (Jashir in Persian), which belongs to the Umbelliferae family, consists of about 30 species [16]. Some of Prangos species are used in traditional medicine as emollient, carminative, tonic, anti-flatulent, anthelmintic, antifungal and antibacterial agents. *Prangos ferulacea* leaves have been used to treat digestive disease and shows no toxicity [17]. In addition, the leaf of *Prangos ferulacea* is consumed for gastrointestinal disorders in traditional medicine [18]. In some study has been shown that the *Prangos ferulacea* is rich sources of antioxidants, including coumarines, flavonoids, alkaloids, umbelliferon, monoterpenes[19].

Nowadays, the world market for functional foods and nutraceuticals is large and growing. The characteristic of these three herbal in terms of bioactive compounds and characteristic flavor was considered to have a potential for use as functional food and value added processed products. In the present study, extracts of *Cichorium intybus*, *Dorema aucheri* and *Prangos ferulacea* evaluated for their antimicrobial activities against some food born pathogens.

**MATERIALS AND METHODS**

**Preparation of the Spices Extracts**

Aerial parts of *Cichorium intybus*, *Dorema aucheri* and *Prangos ferulacea* collected from Dena Mountain area in Southwestern of Iran in May 2013 and identified at Faculty of Pharmacy, Shiraz University Medical Sciences. The alcoholic extracts were prepared by double maceration in 95% methanol for 4 days. Solvent was removed from filtered extract under reduced pressure to produce a thick dark green extract. The resulting extract was kept in a dark and cold place in sterile vials for further tests.

**Bacterial strain, culture conditions, and preparation of inocula**

Nine standard bacterial strains were used as follow, 4 Gram positive (*Staphylococcus aureus* ATCC 25923, *Bacillus subtilis* ATCC 15561, *Bacillus cereus* ATCC 14579 and *Listeria monocytogenes* ATCC 19115), 5 Gram negative bacteria (*Escherichia coli* O157: H7 ATCC 43895, *Citrobacter freundii* ATCC 43864, *Salmonella enteritidis* ATCC 13076, *Enterococcus aerogenes* ATCC 13048 and *Klebsiella pneumoniae* ATCC 3583). A pure culture of the strains were maintained at -20 °C in Brain Heart Infusion broth (Merck) containing 25% glycerol, which was thawed before use.

To prepare bacterial inocula, 0.1 ml of the thawed cultures was transferred to 10 ml of sterile Tryptic Soy Broth (TSB, Merck) and was incubated overnight at 37 °C. A Tryptic Soy Agar (TSA, Merck) plates were streaked from these broths and incubated overnight at 37 °C.

To establish a correlation between the colony forming unit (CFU) ml⁻¹ and absorbance of the dilutions at 600 nm, a standard curve was prepared. A single colony from the TSA plates was inoculated into 10 ml of TSB and was incubated over night at 37 °C. A volume of 0.1 ml of the suspensions was transferred to 10 ml of TSB and was incubated at 37 °C for about 18 h. The cultures were harvested at the midlog phase, three times pelleted by centrifugation at 3000g for 20 min and washed in 0.1% peptone–water. Final cell pellets were resuspended in 10 ml of 0.1% peptone–water. Five twofold serial dilutions were made and their absorbances were measured at 600nm. To determine the log₁₀ CFU ml⁻¹ corresponding to the absorbance of that same dilution, viable cell counts were performed in duplicate by plating serial dilutions onto TSA and incubating the plates at 37 °C for 24 h.

**Antimicrobial assay using Disc diffusion method**

The antimicrobial assay of spices was performed by disc diffusion method as described by Kirby-Bauer [20]. All the experiments were performed under sterile conditions. The Tryptic Soy Agar (TSA) plates were inoculated separately with 10⁇ CFU of each test bacterial strain culture and evenly spread by sterile L shaped glass rod on entire surface of
each plate. The sterile discs (5 mm diameter) were dipped aseptically in different extracts for one minute and placed over nutrient agar plates seeded with bacterial culture. The plates were left at ambient temperature for 15 minutes and then incubated at 37°C for 16 hours and observed for zone of inhibition. The antimicrobial activities of discs were determined by measuring the zone of inhibition expressed in millimeter. Antimicrobial assay was performed in triplicate with each bacterial strain.

**Microtiter broth dilution method**

Microtiter broth dilution method was performed at described previously [21]. Briefly, overnight cultures of bacteria in TSB were sub-cultured and grown for 24 hours. The cells were diluted with TSB to 1x10⁶ colony-forming units per ml (CFU/ml). 100 µl of TSB was added into each of the wells of the first column of a microtiter plate. 100 µl of each filter-sterilized extract was added to the first well of the microtiter plate and then serially diluted (2-fold) to the last well of the plate (or in a horizontal manner to the last well of the plate). Finally each well received 100 µl of 1x10⁶ (CFU/ml) of selected bacteria. The plate was sealed and incubated 24 hours at 37 °C. Then, their absorbance read at 600 nm by microplate reader (BMG Labtech, Germany). Growth inhibition for each extract was calculated based on the following relationship (or equation):

\[
\text{Inhibition growth (\%) = \frac{\text{Fraction absorbance – control negative absorbance}}{\text{Control positive absorbance - control negative absorbance}} \times 100}
\]

**Statistical analysis**

All the experiments were performed in triplicate. Data were analyzed using One-way Analysis of Variance (ANOVA) by the SPSS software (version 21). Duncan’s multiple range test was used as a post hoc test. Correlation between the results of two methods was determined. P < 0.05 was considered as a level of significance.

**RESULT AND DISCUSSION**

The results of antibacterial activity of methanolic extracts of selected plant extracts against 9 laboratory strains of microorganisms, including 4 Gram positive and 5 Gram negative bacteria, by the agar diffusion method and Microtiter broth dilution method are presented in tables 1 & 2.

![Microtiter broth dilution method](image)

The zone of inhibition varied from 5 to 16 mm. *Salmonella enteritidis* and *Citrobacter freundii* were the most sensitive to all extracts. The antibacterial effect of *Dorema aucheri* and *Prangos ferulacea* were more than *Cichorium intybus* for *Salmonella enteritidis* and *Enterococcus aerogenes*. *Cichorium intybus* and *Prangos ferulacea* showed more antibacterial effect than *Dorema aucheri* for *E. coli*, *Staph. aureus* and *Listeria monocytogenes*. *Cichorium intybus* and *Prangos ferulacea* produced higher zone of inhibition than *Dorema aucheri* for *Klebsiella pneumonia* and *Cichorium intybus* showed the most antibacterial effect on *Bacillus subtilis*.

The results of Micro titer broth dilution method were in agreement to the antimicrobial assay using Disc diffusion method. The pearson correlation coefficient between two methods was 0.87 (p < 0.01).

Medicinal plants and their extracts were used as first medicines since ancient times. Plants may be an important source of potentially useful structures for the development of new chemotherapeutic agents [22]. The first step towards this goal is the in vitro screening of plant extracts for their bioactivity.
The increase in the number of antibiotic resistant bacteria is no longer matched by expansion in the arsenal of agents available to treat infections. Plants may provide natural sources of antimicrobial drugs that will/or provide novel or lead compounds that may be employed in controlling some infections globally [23].

Each of the extract tested in the present study displayed antibacterial activity on the all bacterial strains. However differences were observed between antibacterial activities of the extracts. Chicory shows significant antibacterial activity that may be due to the presence of many potent compounds such as inulin, bitter sesquiterpene lactones, coumarins, flavonoids, etc. The methanolic extracts of chicory showed a good inhibitory effect against the studied bacteria except Enterococcus aerogenes. In general, gram- negative bacteria were more sensitive than gram-positive bacteria. Dorema aucheri have some anti-bacterial component such as terpene, flavonoids and phenolic compounds [24]; Antimicrobial activity of the Dorema aucheri extract can be attributed to the high amounts of phenolic compounds, such as p-coumaric and caffeic acid [25]. Phytochemical examinations of Prangos ferulacea have led to identifying and extracting some coumarines, alkaloids, flavonoids, terpenoids, α-pinene, monoterpene, sesquiterpenes, and coumarines have been detected [26]. These components have some anti-bacterial effect on gram negative and gram positive bacteria.

These antibacterial components have shown significant antibacterial activity against both gram negative and gram positive effect. Antimicrobial activity of flavonoids results from the ability to form complexes with bacterial cell wall, preventing the growth of microorganisms. To apply their antimicrobial activity, phenolic compounds inhibit enzyme activity through reacting with their sulfhydryl groups or through nonspecific interactions with protein. With respect to antibacterial mechanism of plant extracts, it is shown that polyphenols are capable of forming heavy soluble complexes with proteins, thus binding to bacteria and destroying bacterial cell surface acceptors [25].

These differences could be due to the differences in the chemical composition of these extracts as the secondary metabolites of plants have many effects including antibacterial and antiviral properties [27, 28].

This research indicates that Dorema aucheri have antibacterial effects more than Cichorium intybus and Prangos ferulacea against a number of food spoilage and pathogenic bacteria. Previously, the chemical compounds in the essential oil of Prangos ferulacea were identified and its antimicrobial properties have been shown[29]. In total, the bacteria isolate Bacillus subtilis showed the lowest sensitivity to all of the plant extract. Comparison of findings of different studies seems complicated because the results are affected by many factors such as incubation temperature and time, pH and type of culture medium, microbial growth phase, and volume of medium. Also, chemical composition, type, and mechanism of action of phenolic compounds of each extract are among factors which make difference in the results of the antimicrobial activity of the solvents [30].

CONCLUSION

According to the result, using natural products as antibacterial substances is a proper method for controlling pathogenic bacteria and increasing food shelf life. The results of the present study support the traditional use of the studied plants in the treatment of bacterial infections. Their antibacterial properties indicate that they can be introduced as a replacement antibiotic to treatment and complementary therapy.
